

KRC Pune Offline Windows Application: Response to KRC IT Team Information Request

Product: KRC Pune, VR / Amenities Sales Experience Application (offline Windows desktop app) **Vendor:** Fute Services **Document date:** 16 July 2026 **Prepared by:** Fute Services **Status:** Draft, pending vendor sign-off before release to KRC

1. Executive summary: an offline Windows application

KRC Pune is a standalone Windows desktop application built with Electron and React. It is distributed as an NSIS installer and runs on sales-lounge and presentation machines.

One fact shapes the whole of this response. The application has no backend, no API, no database, no user accounts, and no network communication of any kind once it is installed. Every piece of content it displays, including the 360-degree panoramas, floor plans, videos, brochure and inventory data, is bundled inside the installer and read from the local disk. The application will run correctly on a machine that has never been connected to a network.

We verified this against the compiled production bundle rather than relying on the source code alone, because the source contains some legacy material that no longer ships. The evidence is set out in section 4.

This architecture is why several of the items you requested are not applicable rather than outstanding. We have answered each one individually and given our reasoning, so that your team can confirm or challenge the conclusion rather than simply take our word for it.

2. Point-by-point response

#	Request	Response	Reference
1	Network architecture diagram	Provided	01-network-architecture.pdf
2	Data / information flow diagram	Provided	02-data-flow.pdf
3	Mobile app VAPT report	Not applicable, no mobile application exists	03-security-scope.pdf , section 2
4	Mobile app source code review report	Not applicable, no mobile application exists	03-security-scope.pdf , section 2
5	API VAPT report	Not applicable, the offline Windows app ships no API and makes no API calls	03-security-scope.pdf , section 3
6	Project manager SPOC	Being confirmed by Fute Services management, to be shared separately	Section 3
7	NDA (POC) and MSA (onboarded vendor) with KRC	Handled by Fute Services legal and contracts, to be shared separately	Section 3

3. Items handled outside this pack

Items 6 and 7 cannot be answered from the codebase, so they sit with the business rather than with engineering. Both will be shared with your team directly rather than through this document.

The project manager SPOC, including the escalation contact and working hours, is being confirmed by Fute Services management and will be sent to you separately.

The NDA and MSA are legal instruments, so we have deliberately not drafted them here. They are with the Fute Services legal and contracts owner. An NDA applies if the engagement is a POC, and an MSA applies if Fute Services is an onboarded vendor. Before anything new is signed, it is worth checking with KRC procurement whether an NDA or MSA is already executed between Fute Services and K Raheja Corp under an existing vendor relationship. If one is, we would share the executed copy and its reference number instead.

One note on how to read this pack. The technical content is accurate as of the commit noted below, but it is a vendor self-declaration, not a third-party certification, and it should not be presented as one.

4. Basis of assessment

The statements in this pack come from direct inspection of the repository and the production build of the offline Windows application. They are not drawn from existing documentation or recollection.

What we checked	How	What we found
External network calls in the shipped app	Scanned the compiled bundle (<code>code/dist/assets/</code>) for outbound hosts	No external service hosts. The only matches are documentation URLs inside third-party library comments and error strings (react.dev, reactrouter.com, mui.com)
Data source	Traced the data imports of every routed page	All read <code>src/data/offlineApi.ts</code> , which imports static local JSON
Dead versus live code	Static import-reachability trace from the entry point <code>src/main.tsx</code>	Only 46 of 96 code files are reachable. Every backend-referencing module is unreachable and is never bundled. See <code>03-security-scope.pdf</code> , section 3.1
360-degree VR viewer	<code>code/dist/index.html</code>	Pannellum is vendored locally (<code>./vendor/pannellum.js</code>), not loaded from a CDN
Map	<code>src/pages/Location/MapboxMap.tsx</code>	Despite the filename there is no Mapbox SDK. The screen renders a bundled local MP4 with static image markers
Local data storage	Searched for <code>localStorage</code> , <code>sessionStorage</code> , <code>indexedDB</code> , <code>document.cookie</code>	None present
User input and PII capture	Searched for form, input and submit handlers across routed pages	None present
Telemetry and analytics	Searched for analytics, gtag, sentry, telemetry	None present
Electron hardening	<code>code/electron/main.cjs</code>	Context isolation on, Node integration off, no-op preload

Repository: <https://github.com/Fute-Services/krpune> Assessed at commit: `5876920` , branch `main`

Any material change to the above invalidates this pack and requires it to be reissued. Re-enabling a live backend would be the obvious example. Section 3.1 of the scope statement explains why that caveat matters more than it might appear.
